# **FACE**

## **Data Types**

# **Data Types**

#### **Primitive data-types**

- byte
- int
- short
- long
- char
- Boolea
- n
- float
- daubla

#### Non-primitive data-types

- Strings
- Arrays
- Classes

•••

# **Primitive Data Types**

Data – Type	Size	Description
byte	1 byte	Stores whole numbers from -128 to 127
int	4 bytes	Stores whole numbers from -2,147,483,648 to 2,147,483,647
short	2 bytes	Stores whole numbers from -32,768 to 32,767
long	8 bytes	Stores whole numbers from -9,223.372,036.854,775.808 to 9,223.372,036,854,775,808
char	2 bytes	Stores a single character/letter
boolean	1 byte	Stores true or false values
float	4 bytes	Stores fractional numbers from 3.4e-038 to 3.4e+038. Sufficient for storing 6 to 7 decimal digits
double	8 bytes	Stores fractional numbers from 1.7e-308 to 1.7e+038. Sufficient for storing 15 decimal digits

# **BYTE**

- Byte stores from -128 and 127.
- Can be used instead of int or other integer types to save memory.

```
byte myNum = 100;
System.out.println(myNum);
```

#### **SHORT**

short stores from -32768 to 32767:

```
short myNum = 5000;
System.out.println(myNum);
```

#### INT

- int stores from -2147483648 to 2147483647.
- preferred data type when we create variables with a numeric value.

```
int myNum = 100000;
System.out.println(myNum);
```

## LONG

- long stores from -9223372036854775808 to 9223372036854775808.
- Used when int is not large enough to store the value.
- you should end the value with an "L":

```
long myNum = 1500000000L;
System.out.println(myNum);
```

# **Floating Point Types**

#### **FLOAT**

- float can store fractional numbers from 3.4e-038 to 3.4e+038.
- should end the value with an "f":

```
float myNum = 5.75f;
System.out.println(myNum);
```

#### **DOUBLE**

- Double can store fractional numbers from 1.7e-308 to 1.7e+038.
- you should end the value with a "d":

```
double myNum = 19.99d;
System.out.println(myNum);
```

## Use float or double?

#### **BOOLEAN**

- declared with the boolean keyword
- can only take the values true or false:

```
boolean isJavaFun = true;
boolean isFishTasty = false;
System.out.println(isJavaFun);
System.out.println(isFishTasty);
```

## **STRING**

- The String data type is used to store a sequence of characters (text).
- String values must be surrounded by double quotes:

```
String greeting = "Hello World";
System.out.println(greeting);
```

#### **CHARACTER**

- The char data type is used to store a **single** character.
- A char value must be surrounded by single quotes, like 'A' or 'c':

```
char myGrade = 'B';
System.out.println(myGrade);
```

#### WHY CHAR REQUIRES 2 BYTES IN JAVA?

## IS STRING A NINTH TYPE?

#### WHY DO WE NEED DATA-TYPES?

IS IT REQUIRED?

## **VARIABLES**

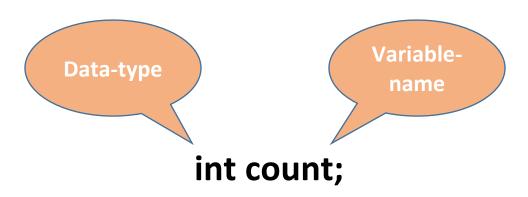

#### What is a variable?

- A variable which holds value, during the life of a Java program.
- Every variable is assigned a **data type** which designates the type and quantity of value it can hold.
- In order to use a variable in a program you to need to perform 2 steps
- --Variable Declaration
- --Variable Initialization

## Variable Declaration

To declare a variable, you must specify the data type & give the variable a unique name.

To initialize a variable, you must assign it a valid value.

**count=100**;

Container named "count" holding a value 100

You can combine variable declaration and initialization.

int count=100;

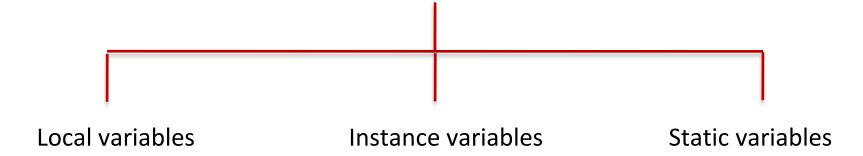

#### NAMING CONVENTION OF VARIABLES

- can start with underscore('\_') but not with digits.
- Should be mnemonic i.e, designed to indicate to the casual observer the intent of its use.
- Can use \_(underscore), digits and letters.
- Should not use any reserved word.

#### **TYPES OF VARIABLES**

## Consider this code snippet

```
class Guru99
         int data = 99; //instance variable
         static int a = 1; //static variable
         void method()
                   int b = 90; //local variable
```

#### Non-static variable V/S Static variable

#### Non-static variable

- 1. Memory is allocated multiple time whenever a new object is created.
- 2. Non-static variable also known as instance variable while because memory is allocated whenever instance is created.
- 3. Non-static variable are specific to an object
- 4. Non-static variable can access with object reference.

#### Static variable

- 1. Memory is allocated for these variable only once in the program.
- 2. Memory is allocated at the time of loading of class so that these are also known as class variable.
- 3. Static variable are common for every object that means there memory location can be sharable by every object reference or same class.
- 4. Static variable can access with class reference.

## WHAT IS WIDENING?

## Consider this code snippet

```
public class Test
{
    public static void main(String[] args)
    {
        System.out.print("Y" + "O");
        System.out.print('L' + 'O');
    }
}
```

# Can you predict the output?

```
YOL
O
YO15
```

## Now, try to predict the output

```
public class Test
  public static void main(String[] args)
    System.out.print("Y" + "O");
    System.out.print('L');
    System.out.print('O');
```

YOLO

#### **RULES FOR WIDENING PRIMITVE CONVERSION**

- The result of adding Java chars, shorts or bytes is an int.
- If either operand is of type double, the other is converted to double.
- Otherwise, if either operand is of type float, the other is converted to float.
- Otherwise, if either operand is of type long, the other is converted to long.
- Otherwise, both operands are converted to type int

## WHAT IS NARROWING?

#### NARROWING OR EXPLICIT TYPE-CASTING

If we want to assign a value of larger data type to a smaller data type we perform explicit type casting or narrowing.

- This is useful for incompatible data types where automatic conversion cannot be done.
- Here, target-type specifies the desired type to convert the specified value to.

## **Guess the output**

```
public class Test
 public static void main(String[] argv)
  char ch = 'c';
  int num = 88;
  ch = num;
```

**Error** 

# Variable Initialization Now, try to predict the output
